Transitions in Programming Models

Luca Cardelli

Microsoft Research
Significant Transitions

• Programming languages (PLs)
  – They evolve slowly and occasionally
  – But new *programming models* are invented routinely
    • As domain-specific libraries or API’s
    • As program analysis tools
    • As language extensions

• Transitions
  – Significant transitions in programming models eventually “precipitate” into new programming languages (unpredictably)
  – We can watch out for significant transitions in programming models
New Programming Models

• We are in the middle of a transition in programming models (and eventually PLs)
  – More radical than C to C++
    • Brought more robust data structures (objects)
  – More radical than C++ to Java
    • Brought more robust control flows (strong typing)
• We now have a Cambrian explosion of programming models.
  – Lots of badly misshaped things are going to evolve before architectures settle down.
  – What’s on the other side of the transition?
Transitions in 3 (related) areas

• A new emphasis on computation on WANs
  – Wide area data integration
    • XML is “net data”. *XML API’s.*
    • Need to integrate this new data into PL data structures.
  – Wide area flow integration
    • Messages nor RPC, schedules not threads. *Messaging API’s.*
    • Need to integrate these new flows into PL control constructs.
  – Wide area security integration
    • Access control, data protection. *Security and privacy API’s.*
    • Need to integrate security properties into PL assertions.

• Impact
  – Disruptive transitions: not easy to convert these API’s into extensions of existing PLs.
  – Ideal topics for research.
• Wouldn't it be nice to "program directly against the schema" in a well-typed way?
  – PL data has traditionally been "triangular" (trees), while persistent data has traditionally been "square" (tables)
  – This has caused huge integration problems, known as the “impedance mismatch” in data base programming languages
  – Now, *BIG NEWS*, persistent data (XML) is triangular too!
  – New opportunity for PL integration
  – However, the type systems for PL data (based on tree matching) and XML (based on tree automata) are still deeply incompatible
Flow Integration

• Wouldn’t it be nice to hide concurrency from programmers?
  – SQL does it well
  – UI packages do it fine
  – RPC does it ok
  – But we are moving towards more asynchrony, i.e. towards more visible concurrency (e-commerce scripts and languages, etc.)
  – *You can hide all concurrency some of the time, and you can hide some concurrency all the time, but you can’t hide all concurrency all the time*
  – Asynchronous message-based concurrency does not fit easily with more traditional shared-memory synchronous concurrency control
Security Integration

- Wouldn’t it be nice to have automatic security?
  - It’s an applet. Sits is a sandbox. End of story.
  - Ok, what about *semi-automatic* security? Explicitly grant/require permissions. (Stack walking etc.)
  - Leads to emerging “sophisticated” access models that programmers do not understand reliably.
How to Integrate Transitions

• New programming models often require new kinds of analysis.
  – Domain Specific Languages: PLs equipped with specialized analysis for specific programming models
  – E.g. SQL (both data and concurrency optimization), security policy languages

• But some transitions go beyond DSL’s
  – C++ was not just a DSL for objects, and Java was not just a DSL for type safety
  – Some transitions really require new “general-purpose” languages
  – We need more than an XML DSL, a messaging DSL, a security DSL
Reliability

• Whether or not we merge new programming models into PLs, we need analysis tools for these new situations
  – Data: e.g.: semistructured type/analysis systems
    • “Does the program output match the schema?”
  – Flow: e.g.: behavioral type/analysis system
    • “Does the program respect the protocol?”
  – Security: e.g.: information-flow type/analysis system
    • “Does the program defy policy or leak secrets”

• Analysis tools are critical for software reliability
What can we do about this?

• Assumptions
  – The existing situation is extremely messy
    • How many web services have you deployed lately?
  – Those 3 WAN-related transitions in programming models have a high probability of precipitating into new languages for WAN programming

• Research plan
  – In view of that, try to make some progress in one or more of those areas
Semistructured Data
- TQL, Spatial Data Types ...
- **MS:** *Xen* (Erik Meijer, Wolfram Shulte, Herman Venter, ...)
  - Extends C# with XML-like data types and XML query expressions, integrated with real SQL queries.

Concurrent Flows
- BPEL, Polyphonic C#, Sharpie, Behavioral Types ...
- **MS:** *Highwire* (Greg Meredith, ...)
  - Distributed scheduling language based on $\pi$-calculus and linear logic types.

Security/Privacy/Protocols
- Samoa, Vault ...
- **MS:** *Binder* (John DeTreville)
  - A Logic-Based security language
A Personal Agenda

• Data
  – Description logics (Spatial Logic)
  – Promising technology: Tree automata

• Flows
  – Polyphonic C#
  – Promising technology: Synchronization joins

• Hiding (a very small step towards security/privacy)
  – Trees with hidden labels
  – Promising technology: Name-dependent types
A tree (or graph), unordered (or ordered). With labels on the edges.

Invented for “flexible” data representation, for quasi-regular data like address books and bibliographies.

Adopted by the DB community as a solution to the “database merge” problem: merging databases from uncoordinated (web) sources.

Adopted by W3C as “web data”, then by everybody else.

Abiteboul, Buneman, Suciu: “Data on the Web”
It’s Unusual Data

• Not really arrays/lists:
  – Many children with the same label, instead of indexed children.
  – Mixture of repeated and non repeated labels under a node.

• Not really records:
  – Many children with the same label.
  – Missing/additional fields with no tagging information.

• Not really variants (tagged unions):
  – Labeled but untagged unions.

• Unusual data.
  – Yet, it aims to be the new universal standard for interoperability of programming languages, databases, e-commerce...
Needs Unusual Languages

• New *flexible* types and schemas are required.
  – Based on “regular expressions over trees” reviving techniques from tree-automata theory.

• New processing languages required.
  – Xduce [Pierce, Hosoya], Cduce, …
  – Various web scripting abominations.

• New query languages required. Various approaches:
  – From simple: Existence of paths through the tree.
  – To fuzzy: Is a tree “kind of similar” to another one?
  – To fancy: Is a tree produced by a tree grammar?
  – To popular: SQL for trees/graphs, for some value of “SQL”.

Data Descriptions

• We want to *talk about* data
  – I.e., specify/query/constrain/typecheck the possible structure of data, for many possible reasons:
    • Typing (and typechecking): for language and database use.
    • Constraining (and checking): for policy or integrity use.
    • Querying (and searching): for semistructured database use.
    • Specifying (and verifying): for architecture or design documents.

• A *description* is a formal way of talking about the possible structure of data.
  – We go after a general framework: a very expressive language of descriptions.
  – Combining logical and structural connectives.
  – Special classes of descriptions can be used as types, schemas, constraints, queries, and specifications.
In Cambridge there is (at least) a pub called the Eagle that contains (at least) one empty chair.

In Cambridge there is (nothing but) a pub called the Eagle that contains (nothing but) two empty chairs.
Example: Queries

With match variables $\mathcal{X}$:

Who is really sitting at the Eagle?

\[
\begin{align*}
\text{Eagle[} & \\
\text{chair[\neg 0 \land \mathcal{X}]} & \\
\text{T} & \\
\text{]} \\
\end{align*}
\]

Yes: $\mathcal{X} = John[0]$

Yes: $\mathcal{X} = Mary[0]$

With select-from:

\[
\begin{align*}
\text{from Eagle[...]} & \\
\text{match Eagle[chair[\neg 0 \land \mathcal{X}]} & \\
\text{| T]} & \\
\text{select person[\mathcal{X}]} & \\
\end{align*}
\]

Single result:

\[
\begin{align*}
\text{person[John[0]]} & \\
\text{person[Mary[0]]} & \\
\end{align*}
\]
Example: Policies

“Vertical” implications about nesting

\[
\text{Borders[}
\begin{align*}
\text{Starbucks[...]} & | \\
\text{Books[...]} & | \\
\end{align*}
\text{]} \quad \Rightarrow \\
\text{Borders[Starbucks[T] | T]}
\]

If it’s a Borders, then it must contain a Starbucks

“Business Policy”

“Horizontal” implications about proximity

\[
\text{Smoker[...]} | \\
\text{NonSmoker[...]} | \\
\text{Smoker[...]} \\
\]

\[
\Rightarrow \\
(\text{NonSmoker[T] | T}) \Rightarrow \\
(\text{Smoker[T] | T})
\]

If there is a NonSmoker, then there must be a Smoker nearby

“Social Policy”
Examples: Schemas

- Descriptions are a “very rich type system”. We can comfortably represent various kinds of schemas.

- Ex.: Xduce-like (DTD-like) schemas:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>the empty tree</td>
</tr>
<tr>
<td>( A \mid B )</td>
<td>an ( A ) next to a ( B )</td>
</tr>
<tr>
<td>( A \lor B )</td>
<td>either an ( A ) or a ( B )</td>
</tr>
<tr>
<td>( n[A] )</td>
<td>an edge ( n ) leading to an ( A )</td>
</tr>
<tr>
<td>( A^* )</td>
<td>( \mu X.0 \lor (A \mid X) ) the merge of zero or more ( A )s</td>
</tr>
<tr>
<td>( A^+ )</td>
<td>( A \mid A^* ) the merge of one or more ( A )s</td>
</tr>
<tr>
<td>( A? )</td>
<td>( 0 \lor A ) zero or one ( A )</td>
</tr>
</tbody>
</table>
Current Work

• Longer-term research:
  – Powerful languages of data description, based on spatial logics. Akin to description logics of some time ago, but seen as type systems.
  – Special cases are regular expressions over trees (XML query, etc.)
  – Lots of open problems in this area (typing and subtyping algorithms)
Xen Type System Extensions

(structural)

\[ T ::= N \mid T \[ \] \mid T \{ \} \mid T(\ldots, T, \ldots) \mid T | T \mid T^* \mid [\ldots, T \ m, \ldots] \]

- arrays
- closures
- union
- streams
- tuples (rows)
FLOWS

• Distribution => concurrency + latency
  => asynchrony
  => more concurrency

• Approaches: Message-passing, event-based programming, dataflow models

• Languages: coordination (orchestration) languages, workflow languages
Language Support for Concurrency

- Make invariants and intentions more apparent (part of the interface)
- Good software engineering
- Allows the compiler much more freedom to choose different implementations
- Also helps other tools
.NET today

- Java-style “monitors”
- OS shared memory primitives
- Delegate-based asynchronous calling model
- Hard to understand, use and get right
  - Different models at different scales
  - Support for asynchrony all on the caller side – little help building code to handle messages (must be thread-safe, reactive, and deadlock-free)
Polyphonic C#

• An extension of the C# language with new concurrency constructs
• Based on the join calculus
  – A foundational process calculus like the $\pi$-calculus but better suited to asynchronous, distributed systems
  – First applied to functional languages (JoCaml).
  – It adapts remarkably well to o-o classes and methods.
• A single model which works both for
  – local concurrency (multiple threads on a single machine)
  – distributed concurrency (asynchronous messaging over LAN or WAN)
• It is different. But it’s also a simple extension of familiar o-o notions.
In one slide:

- Objects have both synchronous and asynchronous methods.
- Values are passed by ordinary method calls:
  - If the method is synchronous, the caller blocks until the method returns some result (as usual).
  - If the method is async, the call completes at once and returns void.
- A class defines a collection of chords (synchronization patterns), which define what happens once a particular set of methods have been invoked. One method may appear in several chords.
  - When pending method calls match a pattern, its body runs.
  - If there is no match, the invocations are queued up.
  - If there are several matches, an unspecified pattern is selected.
  - If a pattern containing only async methods fires, the body runs in a new thread.
A simple buffer

class Buffer {
    String get() & async put(String s) {
        return s;
    }
}
A simple buffer

class Buffer {
    String get() & async put(String s) {
        return s;
    }
}

• An ordinary (synchronous) method with no arguments, returning a string.
class Buffer {
    String get() &
    async put(String s) {
        return s;
    }
}

• An ordinary (synchronous) method with no arguments, returning a string
• An asynchronous method (hence returning no result), with a string argument
A simple buffer

```java
class Buffer {
    String get() & async put(String s) {
        return s;
    }
}
```

- An ordinary (synchronous) method with no arguments, returning a string
- An asynchronous method (hence returning no result), with a string argument
- Joined together in a chord
A simple buffer

```java
class Buffer {
    String get() & async put(String s) {
        return s;
    }
}
```

• Calls to `put()` return immediately (but are internally queued if there’s no waiting `get()`).

• Calls to `get()` block until/unless there’s a matching `put()`

• When there’s a match the body runs, returning the argument of the `put()` to the caller of `get()`.

• Exactly which pairs of calls are matched up is unspecified.
A simple buffer

class Buffer {
    String get() & async put(String s) {
        return s;
    }
}

• Does example this involve spawning any threads?
  • No. Though the calls will usually come from different pre-existing threads.

• So is it thread-safe? You don’t seem to have locked anything…
  • Yes. The chord compiles into code which uses locks. (And that doesn’t mean everything is synchronized on the object.)

• Which method gets the returned result?
  • The synchronous one. And there can be at most one of those in a chord.
VAR i: INTEGER;
VAR m: Thread.Mutex;
VAR c: Thread.Condition;

PROCEDURE AcquireExclusive();
BEGIN
    LOCK m DO
        WHILE i # 0 DO Thread.Wait(m,c) END;
        i := -1;
    END;
END AcquireExclusive;

PROCEDURE AcquireShared();
BEGIN
    LOCK m DO
        WHILE i < 0 DO Thread.Wait(m,c) END;
        i := i+1;
    END;
END AcquireShared;

PROCEDURE ReleaseExclusive();
BEGIN
    LOCK m DO
        i := 0; Thread.Broadcast(c);
    END;
END ReleaseExclusive;

PROCEDURE ReleaseShared();
BEGIN
    LOCK m DO
        i := i-1;
        IF i = 0 THEN Thread.Signal(c) END;
    END;
END ReleaseShared;

An integer i represents the lock state:

-1 ↔ 0 ↔ 1 ↔ 2 ↔ 3 ...
(exclusive) (available) (shared)
public class ReaderWriter {
    public void AcquireExclusive() & async Idle() {}
    public void ReleaseExclusive() { Idle(); }

    public void AcquireShared() & async Idle() { S(1); }
    public void AcquireShared() & async S(int n) { S(n+1); }
    public void ReleaseShared() & async S(int n) {
        if (n == 1) Idle(); else S(n-1);
    }

    public ReaderWriter() { Idle(); }
}

A single private message represents the state:

\[
\text{none} \leftrightarrow \text{Idle()} \leftrightarrow S(1) \leftrightarrow S(2) \leftrightarrow S(3) \ldots
\]

(exclusive) (available) (shared)

A pretty transparent description of a simple state machine, as it should be.
A clean, simple, new model for asynchronous concurrency in C#

- Declarative, local synchronization
- Model good for both local and distributed settings
- Efficiently compiled to queues and automata
- Easier to express and enforce concurrency invariants
- Compatible with existing constructs, though they constrain our design somewhat
- Minimalist design – pieces to build whatever complex synchronization behaviours you need
- Solid foundations
- Works well in practice
- Convenient - much better than programming state machines yourself
Implementation

- Translate Polyphonic C# to C#
- Introduce queues for pending calls (holding blocked threads for sync methods, arguments for asyncs)
- Efficient – bitmasks to look for matches
HIDING

• Any kind of security/privacy issue has to do with hiding something
  – Hiding information by encryption
  – Hiding information by access control
  – Hiding private data so it does not escape

• Baby step:
  – How can we support hidden data in a programming language?
  – N.B.: Hiding *pure names* (passwords/ids) not, e.g., hiding numbers
\[ P, Q ::= \]
\[ 0 \]
\[ n[P] \]
\[ P \mid Q \]
\[ (\forall n)P \]
Tree Equivalence (Structural Congruence)

• \((\forall n)(P \mid (\forall n)Q) \equiv ((\forall n)P) \mid ((\forall n)Q)\)

\[
\begin{align*}
\begin{array}{c}
\text{Diagram}
\end{array}
\end{align*}
\]

• \((\forall n)m[P] \equiv m[(\forall n)P] \text{ if } n\neq m\)

\[
\begin{align*}
\begin{array}{c}
\text{Diagram}
\end{array}
\end{align*}
\]
Ex: Local Pointers

• E.g., XML IDREFs

Encoded as (unique) $addr[y[0]]$

Encoded as $ptr[y[0]]$

Anonymous pointer id

$y$

$addr$

$ptr$

$y$
Ex: Unique and Unguessable IDs

an account

anonymous account number

another account

another (guaranteed different) account number

id

checkbook

y
Type Systems for Hidden Names

- *account* : H y. ... *id[y]* ... *checkbook[y]* ...

- These are *name-dependent* types
  - Dependent types: traditionally very hard to handle because of computational effects.
  - But dependent only on “pure names”: no computational effects.
  - Name-dependent types are emerging as a general techniques for handling freshness, hiding, protocols (e.g. Vault), and perhaps security/privacy aspects in type systems.
Conclusions

• New languages
  – Language evolution is driven by wishes.
  – Language adoption is driven by needs.

• We now *badly need* evolution in areas related to WAN-programming.
  – Lots of inelegant need-driven *hacks*.
  – Some interesting *designs* here and there.
  – Let’s put them together into *languages* that are useful for wide-area programming!
